Forward-looking statements

This document contains forward-looking statements. All statements other than statements of historical facts contained in this document, including statements regarding possible or assumed future results of operations, preclinical and clinical studies, business strategies, research and development plans, collaborations and partnerships, regulatory activities and timing thereof, competitive position, potential growth opportunities, use of proceeds and the effects of competition are forward-looking statements. These statements involve known and unknown risks, uncertainties and other important factors that may cause the actual results, performance or achievements of Wave Life Sciences Ltd. (the “Company”) to be materially different from any future results, performance or achievements expressed or implied by the forward-looking statements. In some cases, you can identify forward-looking statements by terms such as “may,” “will,” “should,” “expect,” “plan,” “aim,” “anticipate,” “could,” “intend,” “target,” “project,” “contemplate,” “believe,” “estimate,” “predict,” “potential” or “continue” or the negative of these terms or other similar expressions. The forward-looking statements in this presentation are only predictions. The Company has based these forward-looking statements largely on its current expectations and projections about future events and financial trends that it believes may affect the Company’s business, financial condition and results of operations. These forward-looking statements speak only as of the date of this presentation and are subject to a number of risks, uncertainties and assumptions, including those listed under Risk Factors in the Company’s Form 10-K and other filings with the SEC, some of which cannot be predicted or quantified and some of which are beyond the Company’s control. The events and circumstances reflected in the Company’s forward-looking statements may not be achieved or occur, and actual results could differ materially from those projected in the forward-looking statements. Moreover, the Company operates in a dynamic industry and economy. New risk factors and uncertainties may emerge from time to time, and it is not possible for management to predict all risk factors and uncertainties that the Company may face. Except as required by applicable law, the Company does not plan to publicly update or revise any forward-looking statements contained herein, whether as a result of any new information, future events, changed circumstances or otherwise.

Unlocking RNA editing with PRISM™ to develop AIMers: A-to-I editing oligonucleotides

GalNAc-mediated uptake

PRISM™-driven gains

Substantial and durable editing in NHP liver *in vivo*

Overview

1 Optimizing editing activity with PRISM™

2 Achieving RNA editing in multiple tissues

3 Applications

Overview

- 1 Optimizing editing activity with PRISM™
- 2
- 3

Enhancing editing efficiency across nearest neighbors

Approach: Structure-activity relationship analysis of AIMer backbone, sugar and orphan base

1 Optimizing orphan site base

2 Optimizing sugar and backbone modification pattern

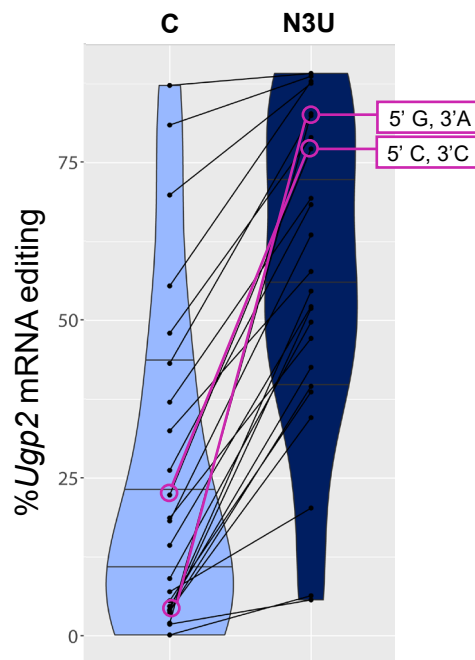

N3U and AIMer-D chemistry mask increase editing across nearest neighbor sequences

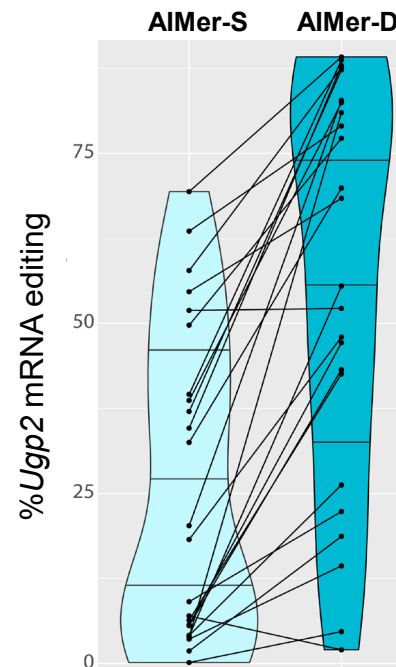

Orphan site base

5' AIMer 3'

Sugar and backbone

5' 3'

N3U supports enhanced editing efficiency *in vivo*

Orphan site base, sugar

5'  3'

Primary mouse hepatocytes
(GalNAc-mediated delivery)

Liver
hADAR-p110 mice

Overview

1

2

Achieving RNA editing in multiple tissues

3

Systemic *in vivo* editing without delivery vehicles

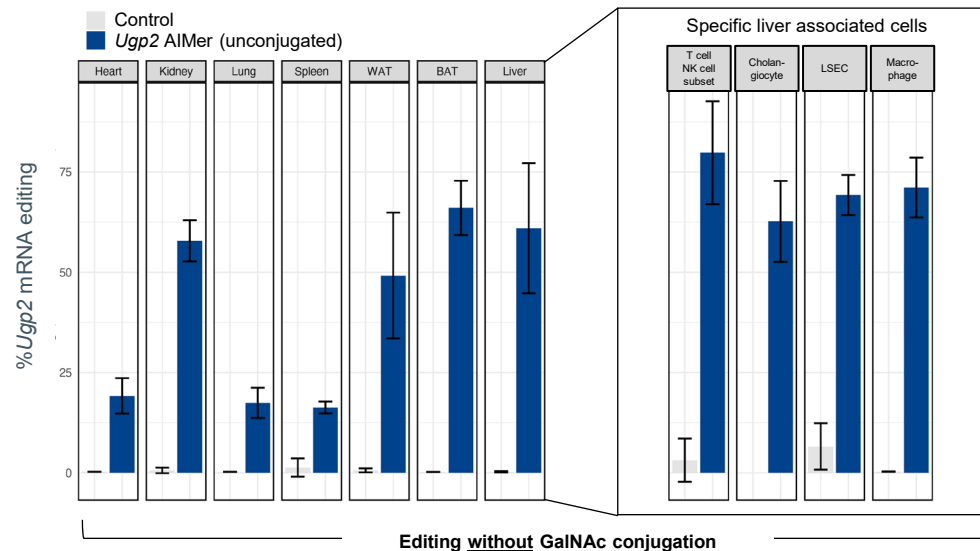

Editing: Potent, durable, specific A → I (G) RNA editing

Delivery: Efficient RNA editing after subcutaneous injection (no delivery vehicle)

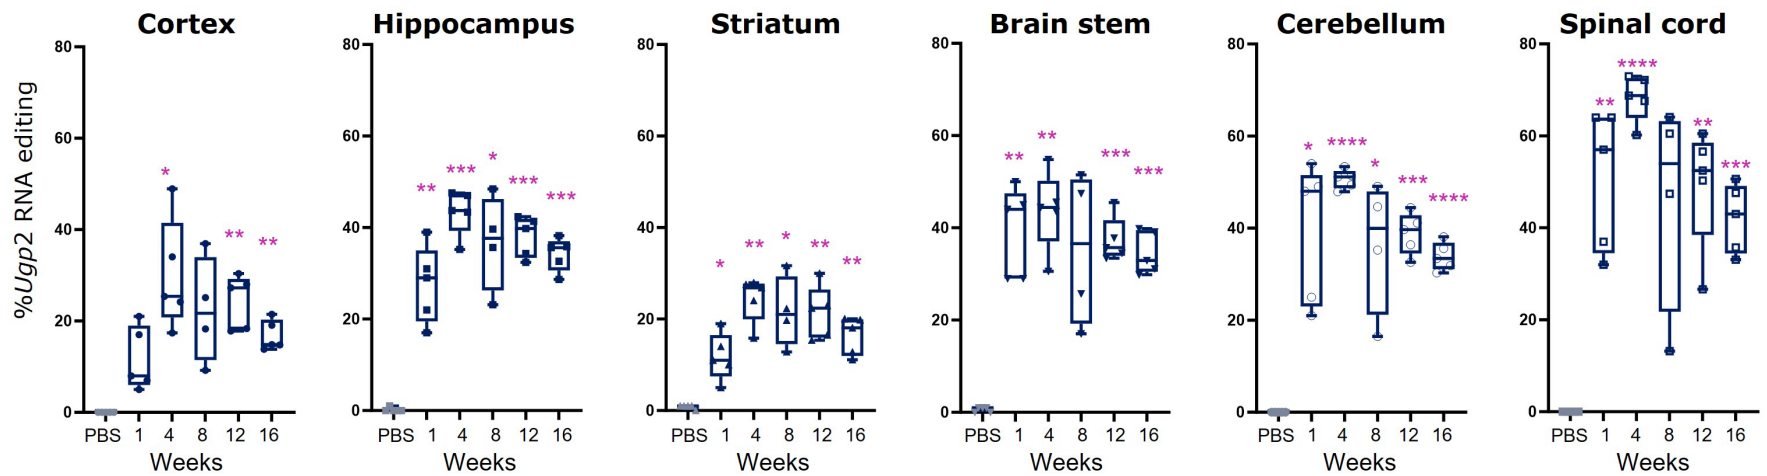

Wild-type mice

Substantial RNA editing across multiple mouse tissues following single subcutaneous dose of *Ugp2* AIMer

Durable editing observed out to 4 months post-single dose

Peak editing observed 4-weeks post-single ICV dose across tissues

	Cortex	Hippocampus	Striatum	Brain stem	Cerebellum	Spinal cord
Peak editing	30%	>40%	25%	>40%	50%	>65%

AIMer directs widespread RNA editing in CNS of NHP

Distribution to Frontal Cortex

In vivo CNS editing in NHP (ACTB, 1 week)

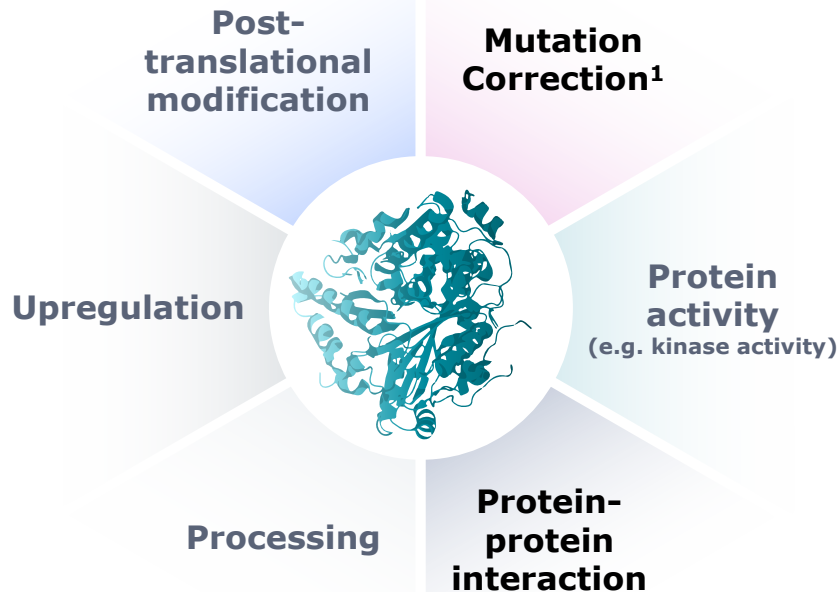

Overview

- 1
- 2
- 3 Applications

ADAR editing for therapeutic applications

ADAR editing of mRNA

Downstream Applications

AIMers can restore protein expression

Mecp2 RNA editing
(Primary cortical neurons, Mecp2^{R168X} KI mouse)

MECP2 protein expression

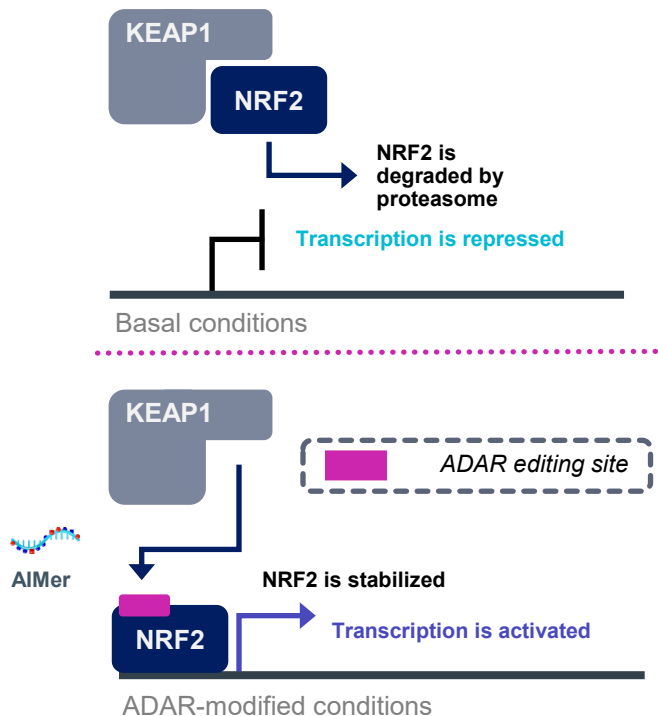

Primary cortical neurons (mouse)

Primary cortical neurons (Mecp2^{R168X} KI mouse)

AIMers disrupt protein-protein interaction *in vivo*

Summary

- Optimized AIMer design enhances editing *in vitro* and *in vivo*
 - Design improvements include N3U orphan base modification and optimization of sugar modification and backbone modification patterns
 - Editing efficiency improved across nearest neighbor combinations
- AIMers support RNA editing across multiple extrahepatic tissues including kidney, lung, and the CNS
- AIMer-based editing in the CNS is observed in mice and NHPs and is durable up to 16 weeks in mice
- AIMers can be used to disrupt protein-protein interactions and restore protein expression.

ABSTRACT

RNA interference (RNAi) represents a powerful tool for the silencing of genes and has been widely used in research and clinical applications. The efficacy of RNAi is highly dependent on the design of the siRNA backbone. In this study, we investigated the impact of stereorec chimeric backbone chemistries on the potency and durability of gene silencing by RNA interference. We synthesized a library of siRNAs with different backbone chemistries and evaluated their silencing potency and durability in a cell-based model. We found that the stereorec chimeric backbone chemistries significantly improved the silencing potency and durability of the siRNAs compared to the standard siRNA backbone. Our results suggest that the stereorec chimeric backbone chemistries are a promising approach for improving the efficacy of RNAi-based gene silencing.

ABSTRACT

Splicing is a critical step in the processing of pre-mRNA and is essential for the production of mature mRNA. Splicing is a complex process that involves the removal of introns and the joining of exons. The efficiency of splicing is highly dependent on the design of the oligonucleotide backbone. In this study, we investigated the impact of backbone chemistry and chirality on the splice switching activity of oligonucleotides. We synthesized a library of oligonucleotides with different backbone chemistries and evaluated their splice switching activity in a cell-based model. We found that the backbone chemistry and chirality significantly impacted the splice switching activity of the oligonucleotides. Our results suggest that the backbone chemistry and chirality are important factors for improving the splice switching activity of oligonucleotides.

ABSTRACT

ADAR-mediated RNA editing is a natural process that occurs in all mammals. It involves the deamination of adenosine to inosine in RNA. This process is essential for the production of mature mRNA and is involved in various biological processes. In this study, we investigated the impact of stereorec chemically modified oligonucleotides on ADAR-mediated RNA editing in non-human primates. We synthesized a library of oligonucleotides with different backbone chemistries and evaluated their impact on ADAR-mediated RNA editing in a cell-based model. We found that the stereorec chemically modified oligonucleotides significantly improved ADAR-mediated RNA editing compared to the standard oligonucleotide backbone. Our results suggest that the stereorec chemically modified oligonucleotides are a promising approach for improving ADAR-mediated RNA editing in non-human primates.
